Why Deploy Anything But Advanced Cabling Technology to Transport High-Speed Services?

The primary distribution ring and trunk section of an HFC network mandates strong cable designed to withstand the rigors of environmental elements. CommScope meets these demands with cable renowned in the cable television industry - $\mathrm{QR}^{*}, \mathrm{MC}^{2^{\circ}}$ and $\mathrm{P} 3^{*}$. Constructions for underground installation feature Migra-Heal ${ }^{\circ}$ floodant to isolate jacket damage and inhibit corrosion. Other available product options include armor, messengers, dual jackets and CableGuard', a patented jacket featuring compartmentalized cells designed to offer excellent cut-through and crush resistance.

## Compelling Reasons to Build With QR

Our patented QR cable is a time-tested design with superior reliability and flexibility. We are so certain of this claim that we offer an unprecedented 10 year warranty on QR. CommScope relies on proven technology and advanced design and development. The end result is a trunk and distribution cable that easily integrates with existing cable plant, but offers the latest advances in performance and reliability.

## QR ${ }^{\text {- }}$ More Miles for Your Money

Here's why leading broadband service providers around the world standardize on $Q R$ as the broadband coaxial transmission cable of choice:

- For less money, QR delivers better electrical and mechanical performance than more expensive traditional cables.
- QR benefits from an engineered connector system that creates a "triple grip" on the cable (center conductor, shield and jacket). This system provides the simplest, quickest and most consistent connector installation yielding extremely high reliability.
- Creatively deployed, QR can reduce the number of actives required in a system to save you even more money.

## P3 ${ }^{\circ}$ - The Cable Upon Which an Industry was Built

P3 has proven robust and reliable through years of successful coaxial installations. Low attenuation and inherent strength make it a good choice for distribution applications. P3 is available with flooding, integrated messengers, armor or a Cable Guard jacket.
$\mathbf{M C}^{\mathbf{2}}$
CommScope is the only U.S. manufacturer of air dielectric cable designed especially for the broadband market. MC ${ }^{2}$ air dielectric composite construction offers a great balance of important cable properties such as attenuation, bending radius, loop resistance and ease of installation.

> PowerFeeder - Cable for the "Always On" Network

> PowerFeeder, a novel coaxial cable optimized for reliable power delivery, features extremely low resistance and minimizes voltage drops over long distances. The low resistance components of PowerFeeder cables play an essential role in the deployment of lifeline telephony and other critical data services. These products enable centralized power supplies and the delivery of power whenever and wherever needed.

Request a FREE Broadband Applications \& Construction Library
CommScope's Broadband Applications \& Construction
Library includes a 4 -piece set of valuable reference manuals plus a DVD containing essential training videos on topics such as connectorization, expansion loop formation and fiber optic splicing. These tools teach you how to protect the integrity of your broadband plant while lowering operating/ installation costs.

## CommScope's <br> Broadband Resource Center"

This repository of experience, knowledge, services \& tools is provided to CommScope customers to assist installers, technicians, engineers, designers or managers of broadband service providers. Tools in various media and formats include: SpanMaster ${ }^{*}$ software for cable sag \& tension calculations; attenuation slide rules; \& call center spec assistance \& review. Call us at 1-866-333-3BRC (3272) or e-mail brc@commscope.com for answers to product questions or issues related to any CommScope broadband product.

CommScope's patented $Q R^{\circ}$ coaxial cable was developed to meet the increasing demands of tomorrow's broadband networks. QR has the highest reliability and flexibility of any Trunk and Distribution coaxial cable, low RF attenuation and an unprecedented 10 year warranty.

All QR cable products offer tough polyethylene jackets and a standardized, environmentally sealed connector interface engineered for reliability and craft friendliness.

QR 320 is optimized for use in multiple dwelling units (MDU) and feeder applications. QR 320 offers unmatched flexibility, reliability and cost effectiveness.

## Standard QR Construction

A precision aluminum strip is formed and continuously RF welded around a high compression micro-cellular foam dielectric core, minimizing RF egress and ingress, and the rigidity common in traditional trunk and distribution coaxial products. The shield is fully bonded to the dielectric core, as is the copper clad aluminum center conductor. A tough polyethylene jacket is applied standard, which enhances cable reliability and allows QR's unique connector technology to form an environmental seal.

Aerial Construction

Setting a New Standard
in Cable Technology!
A clean center conductor after coring is a feature of this product and should be considered normal.

[^6]
## P3 500 Series Cables

Product Descriptions

CommScope's P3 product line is the industry standard by which all coaxial trunk and distribution cables are measured. P3 has been proven robust and reliable by years of successful installations.

P3 500 is optimized for use in broadband feeder plants. Its small size, low attenuation and inherent strength has made it an industry standard.

## Standard P3 Construction

A high precision aluminum outer conductor surrounds a high compression, micro-cellular foam dielectric core. The core contains a fully bonded copper clad center conductor.

## Aerial Construction

| Catalog Number | Description | Cable Weight | Shipping Weight | Standard Length |
| :---: | :---: | :---: | :---: | :---: |
| P3 500 CA | offers all of P3's standard construction features (without a jacket) | $\begin{gathered} 72 \mathrm{lbs} / \mathrm{kft} \\ (107 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{gathered} 97 \mathrm{lbs} / \mathrm{ktt} \\ (144 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{aligned} & 2400 \mathrm{ft} \\ & (732 \mathrm{~m}) \end{aligned}$ |
| P3 500 JCA | offers all of P3's standard construction features | $\begin{gathered} 95 \mathrm{lbs} / \mathrm{ktt} \\ (141 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{gathered} 120 \mathrm{lbs} / \mathrm{kft} \\ (179 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{aligned} & 2400 \mathrm{ft} \\ & (732 \mathrm{~m}) \end{aligned}$ |
| P3 500 JCAM 109 | has an integrated figure 8 galvanized solid steel messenger for self-supporting applications | $\begin{gathered} 134 \mathrm{lbs} / \mathrm{kft} \\ (199 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{gathered} 176 \mathrm{lbs} / \mathrm{kft} \\ (262 \mathrm{~kg} / \mathrm{km}) \end{gathered}$ | $\begin{aligned} & 2400 \mathrm{ft} \\ & (732 \mathrm{~m}) \end{aligned}$ |

Underground Construction

## Setting a New Standard

in Cable Technology!
A clean center conductor after coring is a feature of this product and should be considered normal.

Specifications are subject to change without notice.

CommScope's P3 ${ }^{\circ}$ product line is the industry standard by which all coaxial trunk and distribution cables are measured. P3 has been proven robust and reliable by years of successful installations.

P3 565 is optimized for use in broadband feeder plants. A thinner aluminum shield contributes to lower cable weight, while a slightly larger diameter impacts cable attenuation.

## Standard P3 Construction

A high precision aluminum outer conductor surrounds a high compression, micro-cellular foam dielectric core. The core contains a fully bonded copper clad center conductor.

CommScope's P3 ${ }^{\circ}$ product line is the industry standard by which all coaxial trunk and distribution cables are measured. P3 has been proven robust and reliable by years of successful installations.

P3 750 is optimized for use in broadband distribution plants. Its low attenuation and inherent strength has made it an industry standard.

## Standard P3 Construction

A high precision aluminum outer conductor surrounds a high compression, micro-cellular foam dielectric core. The core contains a fully bonded copper clad center conductor.

## Aerial Construction

| Catalog Number | Description | Cable Weight | Shipping Weight | Standard Length |

## P3 ${ }^{\circ} 840$ Series Cables

Product Descriptions

CommScope's P3 ${ }^{\circ}$ product line is the industry standard by which all coaxial trunk and distribution cables are measured. P3 has been proven robust and reliable by years of successful installations.

P3 840 has been designed for use in broadband trunk \& distribution plants. A thinner aluminum shield contributes to lower cable weight, while a slightly larger diameter impacts cable attenuation.

## Standard P3 Construction

A high precision aluminum outer conductor surrounds a high compression, micro-cellular foam dielectric core. The core contains a fully bonded copper clad center conductor.

## Aerial Construction

Setting a New Standard
in Cable Technology!
A clean center conductor after coring is a feature of this product and should be considered normal.

Specifications are subject to change without notice.

CommScope offers MC2 disc-and-air dielectric coaxial distribution cable in addition to our traditional foam dielectric lines. MC² offers the lowest available attenuation in the smallest diameter cable, thereby maximizing conduit efficiency and/or minimizing HFC plant active requirements. Fully bonded performance and a variety of jacket configurations make $\mathrm{MC}^{2}$ a flexible alternative. Like all CommScope distribution products, $\mathrm{MC}^{2} 500,650$ and 750 are available preinstalled in ConQuest Conduit.

CommScope offers MC2 disc-and-air dielectric coaxial distribution cable in addition to our traditional foam dielectric lines. MC² offers the lowest available attenuation in the smallest diameter cable, thereby maximizing conduit efficiency and/or minimizing HFC plant active requirements. Fully bonded performance and a variety of jacket configurations make $\mathrm{MC}^{2}$ a flexible alternative. Like all CommScope distribution products, $\mathrm{MC}^{2} 500,650$ and 750 are available preinstalled in ConQuest Conduit.

## Weight

284 lbs. per 1000 feet

Power Feeder cable is used for delivery of centralized power in today's networks. Coaxial familiarity and the lowest DC Loop Resistance available in a convenient feeder cable size makes Power Feeder the choice for power delivery.
Copper clad aluminum center conductor; expanded polyethylene dielectric; continuous aluminum outer conductor; polyethylene (PE) jacket, tracers (3 red stripes).

NOTE: Each shipment shall be standard lengths, plus or minus 10\%. Not more than 10\% of shipment shall be other than standard lengths. No length shall be shorter than 2000ff. for MC2 and P3.

## Method of Shipment

Method of shipment at discretion of shipper, unless specified in order.

## Inspection

Inspection and final acceptance shall be made at factory prior to shipment.

## Storing CommScope Cable

Reels of cable should remain properly wrapped to prevent damage during storage. Select a storage location to minimize the chances of damage during cable storage.

If cable is to be stored indoors and a forklift is available, the reels can be stacked on their sides. Trunk reel sizes $35^{\prime \prime} \times 18^{\prime \prime}$ and $42^{\prime \prime} \times 171 / 2^{\prime \prime}$ (flange $\times$ traverse width) can be stacked up to 4 reels high. Other reel sizes may be stacked a maximum 3 reels high. To facilitate stacking and unstacking with a forklift and to prevent damage, place four or more $2^{\prime \prime} \times 4^{\prime \prime}$ spacers under each reel. The spacers should be placed under the bolts of the reel. This will enable the forks to slide safely between the reels and will also prevent moisture from accumulating and damaging the reel.

If cable is to be stored outdoors and a forklift is available, the cable may be stacked as previously described. However, if a forklift is not available, cable can be stored on rolling edge. Reels should be lined up in rows end to end so that the flanges of the reels touch each other.

Cable stored in the outside areas should be stored in a covered area; however if that is unavailable, cable should be covered with plastic, canvas, or other protective covering. Also, the ground should be somewhat level and have good drainage to reduce the possibility of deterioration of the reel flanges.

## Reel Size Example

F = Flange Diameter (in inches)
$\mathbf{D}=$ Drum Diameter (in inches)
$\mathbf{T}=$ Traverse inside distance between flanges (in inches)

Note: $T$ is inside dimension, not overall width

## Notes:

1. An additional 4.0 inches should be added to the traverse width to obtain the total width of the trunk and distribution reel size.

Example: 50" x 24" X 24"
total width will be $28^{\prime \prime}(50 \times 24 \times 28)$.
2. All T\&D reels have an arbor hole diameter of $3^{1} / 8^{\prime \prime}$.

## Formulas for Calculating Shipping Weights

([Standard Reel Length/1000] $\times$ Cable Weight) + Reel Weight $=$ Shipping Weight (In Imperial Units)
(Standard Reel Length $\times$ Cable Weight) + Reel Weight $=$ Shipping Weight (In Metric Units)

Advanced Coring Technology

- Enhanced Mechanical Performance
- Meets/Exceeds ANSI/SCTE, EN50117, IEC and Cenelec
- Fully Backward Compatible
- Identical in Electrical Performance
- Patented

Traditional coaxial trunk and distribution cables require considerable attention to the preparation of the cable end for proper connectorization. Critical to that end preparation is the proper removal of dielectric and bonding compound from the conductors.

The normal process for this requires the craftsman to first core the cable and then clean the center conductor in a second step. CommScope's new $\mathrm{P} 3^{\circ}$ with ACT , and $\mathrm{QR}^{\circ}$ with $\mathrm{ACT}^{\circ}$ cables virtually eliminate the center conductor cleaning step by enabling a clean coring process in which the center conductor is cleaned of dielectric and bonding compound during the coring process.

These cables meet and exceed all ANSI/SCTE, EN50117, IEC and Cenelec testing methods for trunk, feeder, and distribution cables.

P3 ${ }^{\circ}$ and QR $^{\circ}$ with ACT were developed to address a question that has been clearly stated and often repeated by the craftsmen, engineers, and technical operations managers of the broadband industry.

Why must a hardline cable be so difficult and problematic to properly core and prep?

Before the introduction of ACT cables, craftsmen struggled with the cleaning of the center conductor. To remove the remaining dielectric and bonding compound craftsmen have:

- Used a metallic blade, resulting in loss of copper and negatively impacting the skin effect.
- Used a torch to heat up and soften the material, resulting in dielectric melt down inside the cable. This dielectric melt down causes changes in the electrical and mechanical performance characteristics of the cable.
- Used chemical and petroleum based solvents to remove the material, exposing them to a toxic hazard unnecessarily and leaving inappropriate residues on the center conductor.
- Used a center conductor cleaning tool that requires blades to be replaced as they become worn or damaged.
- Used nothing, leaving the dielectric and bonding compound residue and causing poor signal performance and electrical anomalies.

Below is an example of a traditional P3 ${ }^{\circ}$ Cable:

Residual dielectric and bonding compound on conductor affer coring

Below is an example of P3 ${ }^{\circ}$ Cable with $\mathrm{ACT}^{*}$ :

Conductor clean of dielectric and bonding compounds after coring
o ACT cables not only eliminate all of these issues, but also significantly reduce the time needed to core and prep the cable end and make connectorization easier. This is accomplished through the development of an advanced technology bonding agent coupled with CommScope's consistent manufacturing capabilities. This patented formulation leverages the shearing action produced by every coring tool enabling most tools to produce a one pass coring operation leaving the conductors clean of dielectric and bonding compounds. Tools and craft skill may affect the clean coring capabilities.

P3 and QR with ACT are expected to provide system operators with a reduction in truck rolls and labor cost for trunk and distribution plant. This reduction of truck rolls and labor cost is achieved through consistent clean coring. Ensuring that this critical step in the connectorization process is done right the first time every time eliminating many of the issues associated with poor connectorization, thus reducing the need to return to troubled locations to make corrective changes.

# Coaxial Bonding - Optimizing Preparation and Connectorization Technical Report 

O Hardline coaxial cables have been used in the broadband industry for decades. During these years many refinements were made to these cables to produce the optimal cable electrical and mechanical performance. Today, with a better knowledge of processes and recent advancements in material, cables are again being further optimized.

## O Introduction

Coaxial cables have several interface areas between metals and plastics. Each of these interfaces offers a unique set of issues to the user and manufacturer, all related to the bonding of the plastics to the metals. It is bonding that enhances the mechanical performance of a coaxial cable; enabling improved bend performance, core retention, and inhibiting moisture migration.

Just as essential as the cable's mechanical performance is the ability to properly prepare and connectorize a cable. There must be a balance to achieve both with optimal results. This paper will provide an understanding of what trade-offs are made when going to the extremes in bonding, preparation performance, and the optimal zone for a cable to be in.

## Industry Standards

To assure a cable's performance for the user, the industry has adopted standardized test methods and minimum specifications for defining the bond characteristics of coaxial cable.

As a starting point, the SCTE in its "Specification for Trunk, Feeder and Distribution Coaxial Cable" [ANSI/SCTE 15 2006] specifies minimum bond strength between the dielectric and the center conductor defined as "Dielectric Shear Adhesion". The bond strength values vary with cable size, with larger cables having higher bond strength requirements than smaller cables.

| Cable Type | Bond Strength <br> Miminum Pound Force |
| :--- | :--- |
| $\mathbf{P 3}$ |  |
| 500 | 60 |
| 625 | 80 |
| 750 | 90 |
| 875 | 86 |
| $\mathbf{Q R}$ |  |
| 540 | 68 |
| 715 | 90 |
| 860 | 96 |

ANSI/SCTE 15 2001-Table 10.0

Enhanced Mechanical Performance<br>Meets/Exceeds ANSI/SCTE, EN50117,IEC and Cenelec Specifications<br>Fully Backward Compatible<br>Identical Electrical Performance<br>Patented

As an example, a P3 500 cable size has a minimum bond strength requirement of 60 lbs ., while a P3 750 cable size has a requirement of 90 lbs .

Additional important attributes of the bond are identified in this specification. First, a "Dielectric Shrinkback" requirement in which the shrinkback of the dielectric shall shrink no more than 0.250 inches $(6.35 \mathrm{~mm})$ from both ends of the sample following test procedure ASTM D 4565. Second, is the "Cable Static Minimum Bend" tested following ANSI/SCTE 392001.

## The Bond

Typical bond strengths of today's cables well exceed these minimum requirements, being as much as $100 \%$ above that specified by ANSI/SCTE. Such a conservative approach is understandable given that there was no cost penalty to create a bond that performed at such a high level, and that operating at that level eliminated any potential for poor performance due to low bond strength. With excessively high bond strengths, controlling the consistency of the cable's quality is less demanding. The negative impact of this for the cable's user is a difficult preparation and connectorization process.

At the other end of the spectrum are poorly bonded cables that do not meet the specified ANSI/SCTE requirements. The typical cause of low bond strength is attributed to the inability to control a consistent manufacturing process. The negative impact of this for the cable's user is poor core retention, moisture migration, and poor bend performance (kinks easily).

# Coaxial Bonding - Optimizing Preparation and Connectorization Technical Report 

There is an operating range, though, in between these two extremes of performance that facilitates a dielectric bond that will cleanly break away from the center conductor without sacrificing the mechanical aspects of the cable.

CommScope has developed, ACT (Advanced Coring Technology), a patented bonding technology that operates in this window between the extremes. As shown in the chart in Figure 1, it exceeds the SCTE requirements for bond strength and provides for a clean and easy removal of the bonding material.

With this technology, the force exerted by the coring tool is sufficient to cause the dielectric to break away from the center conductor, leaving a clean conductor that typically does not require a second dielectric removal step. The tool and the craftsman can influence this enhanced performance characteristic of the cable, making a one step coring highly repeatable.

In addition to bond strength, the bonding agent also maintains the other key performance criteria of the cable as called out in the SCTE specification. Some of those criteria are listed in Table 1.

| Measure | Passes SCTE <br> Requirement |
| :--- | :---: |
| Center Conductor Bond Strength | $\checkmark$ |
| Center Conductor Corrosion | $\checkmark$ |
| Water Penetration | $\checkmark$ |
| Air Transmission | $\checkmark$ |
| Dielectric Shrink Back | $\checkmark$ |
| Velocity of Propagation | $\checkmark$ |
| Attenuation | $\checkmark$ |
| TABLE 1 - CABLE PERFORMANCE WITH ACT. |  |

Overall this solution provides all of the benefits of water migration deterrence, corrosion prevention, and mechanical performance while eliminating the performance risks associated with center conductor dielectric removal.

## Summary

The bond strength in cable is critical to the mechanical performance of the cable. However, bonding affects more than just the cable's mechanical characteristics, it also impacts the facilitation of cable preparation and connectorization. Finding the balance of bond strength and craft friendliness is accomplished by the development of an advanced technology bonding agent and coupling it with CommScope's consistent manufacturing process controls. This achievement enables the cable to mechanically behave the way it needs to and makes the preparation easier.

## Introduction

Coaxial cable is a composite assembly of various metals and plastics arranged in a manner that creates an efficient wave guide for RF transmission. Coaxial cable manufacturers like CommScope are challenged with the tasks of selecting the appropriate materials for this construction and fitting them together in such a way that the cable will provide optimum electrical and mechanical performance. Electrical performance is evaluated in terms of industry standard measures like attenuation, impedance, capacitance, resistance and structural return loss. Mechanical performance is evaluated in terms of bending radii, ease of handling and compatibility with connectors, which also have industry standard criteria. This report will discuss the application of coaxial bonding, one of the techniques used to achieve certain mechanical performance properties.

Coaxial cable's composite construction has several interface areas between metal and plastic. Each of these interfaces offers a unique set of issues to the user and the manufacturer, and has a unique and industry standard test method to define its effectiveness. These industry standard test methods have been defined and accepted by the SCTE Interface Practices subcommittee, and are recognized as the defining criteria for coaxial cable system performance.

## Single Bonding

A coaxial trunk and distribution cable will typically have a copper clad aluminum center conductor. This conductor interfaces with a foamed polyethylene dielectric material. In years past, differential expansion between the metal and plastic caused pull outs, so an aggressive adhesive precoat is employed today to prevent any differential movement of the center conductor. (See Figure 1.) This precoat also prevents moisture from migrating along the center conductor.

A coaxial cable with this interface bonded may be referred to as single bonded. CommScope catalogs refer to this construction as standard.

The tests utilized to ensure this single bonded precoat is effective measure the force required to remove the center conductor from the dielectric material, as well as the leakage of pressurized air. These test procedures are listed in Table 1.

## Double Bonding

A double bonded cable utilizes an adhesive at the second plastic/metal interface where the dielectric joins the shield. (See Figure 2.) Again, this interface offers a unique set of issues. Differential movement at the dielectric/shield interface is not a concern due to the compression used in cable construction and the large surface area shared. It has been shown, however, that cable bending performance can be improved through the utilization of double bonding, particularly when thinner aluminum shields are employed.

## Double Bonding

FIGURE 3

## Triple Bonding

Triple bonding refers to the additional application of adhesive to the coaxial shield/jacket interface. (See Figure 3) This bond eliminates jacket shrinkage. Advanced connector designs can also eliminate jacket shrink, as in the QR family of cable and connectors. Cable geometry can also force a requirement for triple bonding, as is the case with thin shield P3 type designs. These cables are unable by design to bend tightly, and rely on triple bonding to achieve reasonable bends.

Triple bonding is also limited in its application. Flooded products cannot be triple bonded, since the presence of flooding compounds will defeat adhesives. This fact can lead to bending issues with underground cables which, by design, depend on flooding.

There are no industry standard tests to verify the effectiveness or presence of triple bonding. CommScope catalogs refer to both double and triple bonded products as "bonded", since bending specifications are identical.

34. Cable Bend Test

#### Abstract

S Summary Bonding adhesives are applied at different levels with different constructions, and for unique purposes. The center conductor bond is aggressive to prevent movement and water migration. The dielectric/shield or "double bond" adhesive is optimized to provide bending enhancement while releasing cleanly for connector application. The optional triple bond or jacket bond is only required when a cable's design restricts bending. All of these bonding techniques are best evaluated by industry standard performance criteria, which have been developed to ensure relevant and useful product comparisons and performance.

## Introduction

Coaxial cable, the traditional choice for delivery of video services to the home, is today the choice for delivery of modern multimedia video and data services. Three distinct coaxial distribution technologies exist today - the traditional P3 ${ }^{\circ}$ style coaxial cable, $\mathrm{MC}^{\circ}$ disc-and-air dielectric cable and the newer, precision engineered $Q R^{\circ}$ coaxial cable. This paper will discuss the advantages of this newer technology in building networks for the next century.

## o The History of QR

Until the development of CommScope's QR technology, traditional coaxial cable manufacturing had changed very little from its inception. A coaxial cable begins with a center conductor, typically of copper or copper clad aluminum, which is coated with an extruded plastic dielectric. This 'dielectric core' is extremely tough and flexible, and can literally be tied into knots without changing shape. Unfortunately much of the inherent flexibility of the product is lost when the dielectric core is placed inside a rigid aluminum tube, which makes the coaxial shield.

Rigid aluminum serves as a wonderful RF shield for the coax, and partially serves as a current return path. Unfortunately this shield also makes coaxial trunk and distribution cable stiff, and limits its bending radius.

CommScope engineers determined that if a coaxial cable could be manufactured with a more flexible shield, the strength and flexibility of the dielectric core would better exhibit itself in the performance of the finished coaxial cable. CommScope developed QR with that goal in mind.

QR is manufactured by rolling and forging a precision aluminum strip around the dielectric core in a continuous process. The aluminum strip is more flexible and less work hardened than an aluminum tube. The cable is simultaneously jacketed, providing even greater mechanical enhancement.

## Mechanical Benefits

The precision forged QR shield is less work hardened than a standard coaxial tube, and is much easier to bend and flex. This means a finished cable has a much smaller minimum bending radius, and a much longer flex life in an expansion loop.

Expansion loops are placed into coaxial cable to provide excess cable length required during daily and seasonal cable expansion and contraction. These loops see repeated flexure, and are a primary failure point in coaxial plant. QR's greater flexibility has been shown to increase the life of the cable in an expansion loop by a factor of 2 to 3 . QR precision shield requires less metal by volume than a traditional coaxial cable, which results in a lower cable weight. QR's lower weight, combined with tremendous cable flexibility, makes $Q R$ the easiest cable to install. QR requires proportionally less of its maximum pulling tension to install than a comparably sized rigid aluminum tube product. QR is also a 100\% jacketed product, unlike traditional coaxial products, which may be purchased bare. This jacket provides environmental protection, and has also allowed the development of connectors which grip the cable jacket and form an additional environmental seal at the cable's most vulnerable point - the connector interface.

## Electrical Performance

QR was developed with all these mechanical advantages in mind - and it was also designed with an eye toward electrical enhancement. The electrical advantages of QR include its attenuation and Structural Return Loss (SRL) performance.

## Attenuation

Coaxial attenuation is usually a function of cable size. Larger cables have lower attenuation. The DOD, or the distance from the center conductor to the shield, determines the cable attenuation.

QR was designed with a thinner shield, which allow larger DOD than comparably sized cable. This design allows the attenuation of QR to be lower than the attenuation of a comparable size traditional cable. This fact has caused QR to be referred to as a 'low loss' product for many years.

## Structural Return Loss

Structural Return Loss (SRL) is the result of periodic impedance variations being induced into a coaxial cable. These impedance changes can be due to small fluctuations in diameter or material size. When impedance changes appear periodically in the cable, they will induce a loss at a frequency corresponding to their own frequency.

Great care is taken in coaxial manufacturing to prevent these impedance effects from occurring. The QR process was developed to minimize these impedance effects, and reliably produces cable with the lowest SRL.

## DC Loop Resistance

DC loop resistance is a function of the quantity of metal in a cable. Larger cables have more metal, and a lower DC loop resistance than smaller cables. DC loop resistance is specified in ohms $/ 1000^{\prime}$.

QR cables have less metal in the shield than a comparably sized rigid aluminum cable, and have a higher DC loop resistance for that reason. This is a parameter that should be taken into consideration when a system is being designed, but the designer should also consider the following facts about DC loop resistance.

## Span Resistance

As broadband systems are upgraded, the electronics and corresponding frequencies of operation are changed.
Newer systems operate at much higher frequencies than older systems. At these higher frequencies, coaxial cable attenuation is higher, and the distance between system components is reduced.

Span resistance is the product of the DC loop resistance (ohms/1000') and the span length, measured in feet. It can be shown that as span lengths shorten, the span resistance of a QR cable is equivalent to the old span resistance of a traditional cable, even though the DC loop resistance is higher. (See example below.)

> Multiple Return Paths and Effective DC Loop
> An installed broadband plant completes one portion of a very complex electrical circuit. While DC loop resistance measured in the laboratory is a simple combination of the resistance of the center conductor and shield added together, the effective DC loop resistance seen in the field will be much lower. This is due to the additional current return paths that are added to the coaxial shield through grounding and bonding.

## Example:

Assume a budget of 22 dB between amplifiers.
In a P3 750 plant at 450 MHz , the span can be calculated using the attenuation value:
$1.12 \mathrm{~dB} / 100^{\prime}$ at 450 .
$(22 \mathrm{~dB}) /\left(1.12 \mathrm{~dB} / 100^{\prime}\right) X(100)=1964$ feet span length
The span resistance can be calculated by multiplying the DC loop resistance by the span length
( 0.76 ohms $/ 1000$ ) X (1964 feet) / (1000) $=1.49$ ohms
Now, let's upgrade the plant to 750 MHz , and switch to $Q R 715$, which has an attenuation of $1.49 \mathrm{~dB} / 100^{\prime}$ at 750 MHz , and a loop resistance of .997 ohms $/ 100 \mathrm{~A}^{\prime}$.
$(22 d B) /\left(1.49 d B / 100^{\prime}\right) X(100)=1477$ feet span length
The span is shorter to accommodate the higher frequency.
Now we can calculate the span resistance.
(.997 ohms/1000') X (1477 feet) / (1000) = 1.47 ohms

The QR 715 span, shortened for the higher frequency of operation in the upgrade, has a lower span resistance than the original traditional 750 span.

O In the laboratory, DC loop resistance is measured by allowing current to flow down the center conductor, and back on the shield. The resistance measured, and published, is the resistance of the center conductor plus the resistance of the shield. Larger cables have larger center conductors and larger outer conductors, which have more metal content and lower DC resistance.

In an installed plant, the cable is grounded and bonded to the strand (aerial) or to the electronics and ground blocks (buried). These electrical connections allow current which traveled forward on the center conductor to return to ground through many low resistance paths in addition to the coaxial shield. CommScope's testing has shown that the effective DC loop resistance in an installed plant is much lower than published, and is roughly equivalent for $Q R$ and traditional coax (see the graph below).

## System Design and QR

The design of a system using $Q R$ is no different than when using traditional coax, with the notable exception of the advantages $Q R$ provides.

## Mechanical Considerations

QR has much lower pull tension requirements than traditional coax. This fact will be noticed in longer and easier pulls, either aerial or through conduit. QR blows into conduit readily, and is rugged enough for direct burial. All standard construction practices have been used with QR with great success.

When forming expansion loops, QR's flexibility and ease of pulling require that forming boards or tools be left in place until the adjacent loop is formed, or the loops may pull out. This simple precaution should be a part of all construction manuals.

## Electrical Considerations

QR has lower attenuation than comparably sized traditional products. The published attenuation of QR products must be substituted during system design. In addition, the DC loop resistance of QR should be taken into account during system design, but is rarely an issue given the closer spacing of electronics in today's high bandwidth networks.

Overall, the electrical design of a system using QR is identical to that of any other cable type. QR has attenuation and resistance specifications that vary from traditional coax products, but they simply must be taken into account by the designer, and levels and spacing adjusted accordingly.

## Loop Resistance of Feeder Cable

Effective DC loop includes contribution of strand, neutral ground, etc.

## Telephony Considerations

QR has been successfully deployed in networks designed for broadband telephony as well as CATV. CommScope has customers in both the CATV and telephone industries, and both are using $Q R$.

Telephony designs require additional attention be paid to powering of the system. Reliability of power supplies have raised an interest in centralized powering, a design where the power supplies are focused at the node, rather than spread throughout the system. These centralized power designs generally require that power be expressed out to remote network locations.

CommScope has developed a product for this express power feed, called PowerFeeder. PowerFeeder has the lowest available DC loop resistance, in a convenient feeder cable size. It is ideal for any power only application where neither traditional coax nor $Q R$ is suitable.

Telephony builds can be designed for $Q R$ or traditional coax products with only minor differences in levels and spacing. $Q R$ is more than capable of carrying the higher currents required by telephony. $Q R$ products are qualified at voltages and currents far beyond those used, or even predicted.

## Conclusion

QR is the cable of choice for cost, longevity, ease of use and performance. It has been selected by telephone and CATV companies alike for CATV and telephony builds, in the United States and internationally. No other product can match it's unique blend of performance and cost effectiveness.
